## Research Papers

City Minimum Wages (Job Market Paper)

Local minimum wage laws are becoming common across U.S. cities, and their effects may be different from effects of state or nation-wide minimum wage policies. I study the effect of changes in minimum wages on spatial equilibria in local labor markets. Using residence and workplace data for the U.S., I analyze how commuting, residence and work locations change across city and state borders when minimum wages change on either side of the border. I find that areas that increase minimum wages receive less low-wage commuters, with an elasticity of about -0.3. Minimum wage increases are also associated with employment relocation across borders towards the area that did not increase its minimum wage. I formulate a spatial equilibrium gravity model to explain the distribution of workers between low and high minimum wage areas. I calculate counterfactual equilibria with higher minimum wages for US cities considering increases, highlighting the role of commuting and migration responses. About 2 thirds of the cities considering increases would receive less commuters. These commuting losses are driven by employment relocation, and similar to those suggested by the reduced-form analysis.

Minimum Wages in Formal and Informal Sectors: Evidence from the Colombian crisis (Link)

I estimate the effect of the minimum wage on formal wages, informal wages and employment in Colombia. I exploit an unexpected increase in the real minimum wage during the 1999 Colombian economic crisis to estimate short-term effects of the minimum wage along the distribution of wages in both sectors. I find evidence of wage responses, with a stronger incidence in the formal sector. Markets with a 10 % higher incidence of the minimum wage, measured by the number of workers affected, experienced wage increases of 4 % and 1.3 % in the formal and informal sector, respectively. I find negative employment effects on the informal sector, but no employment effects on the formal sector, and a lack of pass-through across sectors. My results suggest that minimum wages affect the informal labor market directly and not through the formal sector.

Unpacking the MPI: a Decomposition Approach of Changes in Multidimensional Poverty Headcounts (With Carlos Rodríguez-Castelán, José Daniel Trujillo and Daniel Valderrama) (<u>Link</u>)

Multidimensional measures of poverty have become standard as complementary indicators of poverty in many countries. Multidimensional poverty calculations typically comprise three indices: the multidimensional headcount, the average deprivation share among the poor, and the adjusted headcount ratio. While several decomposition methodologies are available for the last index, less attention has been paid to decomposing the multidimensional headcount, despite the attention it receives from policy makers. This paper proposes an application of existing methodologies that decompose welfare aggregates—based on counterfactual simulations—to break up the changes of the multidimensional poverty headcount into

the variation attributed to each of its dimensions. This paper examines the potential issues of using counterfactual simulations in this framework, proposes approaches to assess these issues in real applications, and suggests a methodology based on rank preservation within strata, which performs positively in simulations. The methodology is applied in the context of the recent reduction of multidimensional poverty in Colombia, finding that the dimensions associated with education and health are the main drivers behind the poverty decline.

# Research Papers in Progress

The Efficacy of Hiring Credits in Distressed Areas (with Michael Suher)

We analyze the efficacy of hiring tax credits, particularly in distressed labor markets. These types of programs have proven hard to assess as their introduction at the state level tends to be endogenous to local conditions and future prospects. We conduct an empirical study of a hiring tax credit program implemented in North Carolina in the mid-1990s, which has a quasi-experimental design. Specifically, the 100 counties in the state are ranked each year by a formula trying to capture their economic distress level. The generosity of the tax credits jumps discontinuously at various ranking thresholds. We estimate the impact of the credits using difference in differences and regression discontinuity methods. Our estimates show positive impacts on employment levels of around 3% and fairly sizable impacts on unemployment - a \$10,000 credit leads to a 0.7 percentage point reduction in the unemployment rate.
